Speaker Notes:

State your name clearly. Read the topic number and title exactly as on the exam paper. Pause to let examiners see it. Point to the logo. This is your first impression. (30 seconds)

PRESENTATION AGENDA

01 The Challenge

Why interplanetary communication is hard

02 AETHERIX Architecture

DTN + AI Routing + Quantum Security

03 DTN & Bundle Protocol v7

Store-and-forward networking foundation

04 5-Tier Network Topology

241 nodes across Earth and Mars

05 Optical Link Budget

1550 nm laser performance analysis

06 RL-Based Routing

Multi-agent federated Q-learning

07 Quantum Security (QKD)

BB84/E91 with repeater chains

08 Orbital Mechanics

Contact windows and synodic period

09 Mars Mission Scenario

End-to-end simulation walkthrough

10 Performance Comparison

AETHERIX vs current systems

11 Roadmap & Standards

CCSDS, IETF, deployment phases

12 Conclusion & Q&A

Summary and live demo

Speaker Notes:

Quick overview of what we will cover. 13 topics across 47 slides. About 20 minutes. (20 seconds)

WHAT IS AETHERIX?

Autonomous Extraterrestrial High-throughput Enhancing Routing and Inter-planetary eXchange

What is AETHERIX?

An architecture for delay-tolerant networking (DTN) between Earth and Mars, combining:

- Bundle Protocol v7 (BPv7) via ION-DTN
- Reinforcement Learning routing (replacing static CGR)
- Quantum Key Distribution (QKD) for security
- Hybrid optical/RF communications
- 5-tier topology with 241 nodes

The Problem

- Earth-Mars: 54.6M – 401M km distance
- One-way light delay: 3 – 22 minutes
- Solar conjunction: 2-week total blackout
- TCP/IP fundamentally cannot work
- Current systems: 0.5 – 6 Mbps only

AETHERIX delivers a complete interplanetary networking solution

combining DTN protocols, AI-driven routing, quantum-secure keys, and hybrid optical/RF links for Mars mission support.

10-100×

189

Tests

Speaker Notes:

This slide sets up the narrative arc. First explain what AETHERIX is in plain language - it's like the postal service for interplanetary space. Then pivot to the problem: TCP/IP was never designed for space. 22-minute delays break every assumption. Solar conjunction blackouts. Static routing. Vulnerable crypto. Each problem maps to one of our solutions. (1.5 minutes)

THE DISTANCE

Why Space Communication is Fundamentally Different

Earth → Mars	Distance	Light Time	Data Rate
Perihelion (closest)	54.6M km	~3 min	100-200 Mbps
Average	225M km	~12.5 min	10-20 Mbps
Aphelion (farthest)	401M km	~22 min	2-5 Mbps

TCP/IP Assumption	Space Reality	Impact
RTT < 1 second	6 – 44 min RTT	Timeout failure
Always connected	Scheduled contacts	Connection drops
End-to-end path	No persistent path	Routing impossible
Fast acknowledgments	ACKs take minutes	Window collapse
Low packet loss	High loss (optical)	Retransmit storms

"At aphelion, a single ping-pong takes 44 minutes. No TCP session can survive that. We need an entirely different networking paradigm."

Speaker Notes:
Start with the scale. 54.6M to 401M km. Light itself takes 3-22 minutes one way. TCP/IP was designed for sub-second round trips. In space, by the time a packet acknowledgment returns, the link may be gone. Solar conjunction causes 2-week blackout. This is why NASA calls it Delay-Tolerant Networking. (1.5 minutes)

EARTH-MARS DISTANCE OVER TIME

780-Day Synodic Period

Distance varies 7x from 54.6M to 401M km. Solar conjunction causes ~14 day blackout every 26 months

Speaker Notes:

The distance chart shows the fundamental challenge: a 7x variation over the synodic period. At opposition, 55 million km. At conjunction, over 400 million km with the Sun blocking direct communication.

ONE-WAY LIGHT-TIME DELAY

3–22 Minutes Depending on Distance

Light-time delay drives every protocol design decision in AETHERIX

Speaker Notes:

Light-time delay ranges from 3 minutes at closest approach to 22 minutes at maximum distance. TCP/IP expects sub-second round trips — this is why we need DTN.

THE ANSWER: DELAY-TOLERANT NETWORKING

DTN STORE-AND-FORWARD vs TCP/IP

TCP/IP: END-TO-END CONNECTION (FAILS IN SPACE)

TCP requires end-to-end connectivity — impossible with 3-22 min light-time delays

DTN: STORE-AND-FORWARD (WORKS IN SPACE)

Custody Transfer

Each node takes responsibility for the bundle

Store & Wait

Bundle stored safely until next hop available

Link Status

Intermittent links handled gracefully

THREE CONVERGENCE LAYERS

Deep Space (RFC 5226) mission

Earth (RFC 5242) ent

Optical (RFC 5242) low latency

Speaker Notes:

The key insight: instead of requiring an end-to-end connection like TCP, DTN works like the postal service. Each node takes custody of your data and forwards it when a link becomes available. Three pillars: BPv7 for the protocol, RL for intelligent routing, QKD for security. (1.5 minutes)

SYSTEM ARCHITECTURE

5 Integrated Modules for Interplanetary Communication

Infrastructure

Link budget calculations, optical/RF analysis

Routing

RL agents, BPv7 bundles, forwarding engine

Security

BB84/E91 QKD, repeater chains, privacy amplification

Orbital

Contact windows, Doppler, celestial body database

Simulation

End-to-end scenario engine, policy routing

Layer	Module	Engine	Showcase
Infrastructure	link_budget.py	OpticalLinkBudget	Earth-Mars scenarios
Routing	rl_agent.py	RLRoutingAgent	Federated Q-learning
Security	qkd.py	BB84/E91	Quantum key exchange
Orbital	contact_windows.py	ContactPredictor	Synodic period
Simulation	simulator.py	SimEngine	Full mission sim

Speaker Notes:
Show the architecture. Six core modules feed into the simulation engine, which feeds the web showcase. Standards compliance at the bottom. Point to each module as you explain. (1 minute)

SYSTEM ARCHITECTURE DIAGRAM

Speaker Notes:
Architecture diagram showing source modules feeding simulation engine and web demos.

BUNDLE PROTOCOL v7 — DEEP DIVE

RFC 9171 — The Foundation of Interplanetary Networking

APPLICATION LAYER

Science data, commands, imagery

BUNDLE PROTOCOL v7 (RFC 9171)

Store-and-Forward | Custody Transfer | Priority (P0–P4)

CONVERGENCE LAYERS

LTP (deep space) | TCPCL (Earth) | UDP-CL (optical ISL)

PHYSICAL LAYER

Optical 1550nm (2–200 Mbps) | RF Ka-band | UHF (surface)

HOW IT WORKS

1. Source creates bundle (payload + metadata + lifetime)
2. Forward to next hop when link becomes available
3. Store locally during outages and disruptions
4. Custody transfer — next node accepts responsibility
5. Repeat hop-by-hop until destination reached

STANDARDS COMPLIANCE

- RFC 9171 — Bundle Protocol Version 7
- RFC 4838 — DTN Architecture
- RFC 5326 — Licklider Transmission Protocol
- RFC 9172 — Bundle Protocol Security (BPSec)
- CCSDS 734.2-B-1 — CCSDS Bundle Protocol
- CCSDS 734.3-B-1 — Schedule-Aware Bundle Routing

Priority	Name	Delay Target	Example
P0	Emergency	< 1 min	Anomaly alerts
P1	Expedited	< 30 min	Solar storm warnings
P2	Standard	< 24 hrs	Science data
P3	Normal	< 7 days	Telemetry
P4	Bulk	< 30 days	Software updates

BUNDLE PRIORITY CLASSES

Bandwidth Allocation Across Priority Levels

P0 Emergency through P4 Bulk: Deadline aware scheduling. Preemption for critical traffic

Speaker Notes:

Priority class distribution showing how bandwidth is allocated. Emergency traffic preempts everything. The deadline-aware scheduler ensures no bandwidth is wasted.

DTN STORE-AND-FORWARD

How Bundles Traverse the Interplanetary Network

DTN STORE-AND-FORWARD vs TCP/IP

TCP/IP: END-TO-END CONNECTION (FAILS IN SPACE)

TCP requires end-to-end connectivity — impossible with 3-22 min light-time delays

DTN: STORE-AND-FORWARD (WORKS IN SPACE)

Speaker Notes:
Walk through the store-and-forward process. Bundle arrives, gets stored, node waits for next contact opportunity, then forwards. If link drops, bundle stays stored and retries. No data loss. This is fundamentally different from TCP's end-to-end retransmission. (1.5 minutes)

5-TIER NETWORK TOPOLOGY

241 Nodes — No Single Point of Failure

TIER 1: Earth Ground (6 nodes)

DSN Goldstone, Madrid, Canberra + Mission Control

TIER 2: Earth Orbital (51 nodes)

3 GEO relays + 48 LEO laser constellation

TIER 3: Deep Space (4 nodes)

ES-L4, ES-L5 Lagrange relays + Transfer orbit

TIER 4: Mars Orbital (4 nodes)

2 Areostationary + 2 polar orbiters

TIER 5: Mars Surface (176 nodes)

Bases, rovers, drones, sensor network

DESIGN PHILOSOPHY

Multiple redundant paths at every tier ensure no single point of failure. Lagrange point relays provide coverage during solar conjunction blackouts. Quantum repeaters co-located at L4/L5 enable end-to-end key distribution.

NODE DISTRIBUTION ACROSS 5 TIERS

241 Nodes Total

Mars Surface (167) is the largest tier. Deep Space (4) provides critical Lagrange relay coverage.

Speaker Notes:

The tier distribution shows where the 241 nodes sit. Mars Surface dominates with 167 nodes. The 4 deep space nodes at Lagrange points are few but critical for conjunction survival.

5-TIER NETWORK — DETAILED BREAKDOWN

AETHERIX NETWORK TOPOLOGY & BFS PATHFINDING

T1: Earth Ground

T2: Earth Orbital

T3: Deep Space

T4: Mars Orbital

T5: Mars Surface

RL Q-Table Heatmap

	Fwd	Store	Drop	Split	Reroute	Wait	Q(s,a) values
N-A	0.92	0.15	0.02	0.08	0.12	0.05	
N-B	0.45	0.78	0.03	0.10	0.25	0.35	
N-C	0.20	0.85	0.01	0.12	0.30	0.40	
ES-L4	0.88	0.20	0.05	0.15	0.10	0.08	
ES-L5	0.35	0.30	0.02	0.18	0.72	0.25	
MRS	0.90	0.10	0.01	0.05	0.08	0.03	
DSN	0.15	0.60	0.01	0.05	0.10	0.55	

Low High Q-value (learned policy)

BFS Shortest Path

Goldstone → GEO-1 → ES-L4 → Areostat-A → Habitat-1

Hops: 4 | Latency: ~13 min

RL agent improves on BFS via
learned link-quality weights

241 Nodes • 5 Tiers • RL-Optimized Routing • BFS Baseline + Q-Learning Enhancement

Speaker Notes:

Visual overview of the 5-tier topology with 3 redundant paths.

5-TIER NETWORK DIAGRAM

241 Nodes from Earth to Mars Surface

Speaker Notes:
Network topology visualization.

OPTICAL COMMUNICATIONS

1550 nm Laser — 10–100× Faster Than RF

200 Mbps

Peak Data Rate

At perihelion (54.6M km)

1550 nm

Wavelength

Telecom heritage lasers

33×

vs Current RF

MRO peak: 6 Mbps

KEY EQUATIONS

$FSPL = (4\pi d/\lambda)^2$ Free-Space Path Loss

$G = (\pi D/\lambda)^2$ Antenna Gain

$P_r = P_t \cdot G_t \cdot G_r / FSPL$ Received Power

Parameter	Value	Rationale
TX Power	5 W (37 dBm)	Space-qualified laser
TX Aperture	22 cm	Mars orbiter class
RX Aperture	1.0 m	DSN-scale telescope
Wavelength	1550 nm	Telecom heritage
Efficiency	0.55	Conservative estimate

Speaker Notes:
RUN THE LIVE DEMO from the Link Budget page. Show the 3 distance scenarios. 1550nm was chosen for telecom heritage and eye safety. FSPL at average distance is -365 dB. The telescope apertures are realistic for spacecraft. RF backup for reliability. (2 minutes)

DATA RATE VS DISTANCE

1550 nm Optical Link Performance

200 Mbps at closest approach to 2 Mbps at maximum distance — 10-100x improvement over RF

Speaker Notes:

Data rate degrades from 200 Mbps at closest approach to 2 Mbps at maximum distance — but even minimum is competitive with current RF systems.

OPTICAL LINK BUDGET BREAKDOWN

Where the Decibels Go

FSPL dominates at -380 to -310 dB. Optical aperture gain recovers >100 dB.

Speaker Notes:

Link budget breakdown showing where the decibels go — free-space path loss is the dominant factor, compensated by high-gain optical apertures.

EARTH-MARS DATA JOURNEY: 7 HOPS

~225 million km · 12.5 min one-way light time

Speaker Notes:

Interactive journey visualization.

LATENCY: TCP vs DTN vs AETHERIX

Protocol Overhead Comparison

DTN adds <5% overhead beyond physical light time. TCP fails catastrophically at interplanetary distances.

Speaker Notes:

Latency comparison showing TCP failing catastrophically, while DTN adds under 5% overhead beyond the physical light-time limit.

DAILY DATA VOLUME COMPARISON

AETHERIX vs Current Systems

10-20x daily data volume improvement over current Mars missions

Speaker Notes:
AETHERIX delivers 10 to 20 times more data per day than current Mars missions.

RL-BASED ROUTING — AI INNOVATION

Multi-Agent Federated Q-Learning Replaces Static CGR

CGR LIMITATIONS

- Static contact plan — no adaptation
- Manual reconfiguration on failure
- Hours to reroute after disruption
- Cannot learn from network history
- No energy optimization

RL AGENT ADVANTAGES

- Adaptive routing from network state
- 4 actions: FORWARD, STORE, DROP, SPLIT
- Reward: $\alpha(\text{delivery}) - \beta(\text{delay}) - \gamma(\text{hops})$
- Federated learning across agents
- Auto-recovery in seconds, not hours

97%

Delivery Ratio

+5% vs CGR

-20%

Delivery Time

1.2× light-time

3600×

Recovery Speed

Auto vs manual

Speaker Notes:

CGR is what NASA uses today. It's static - you have to pre-compute schedules. Our RL agent learns from experience. 8 state variables, 4 actions. The reward function balances delivery probability against delay, hops, drops, and energy. Multi-agent federated learning means agents at each node share knowledge. (2 minutes)

RL ROUTING Q-VALUE HEATMAP

Convergence of Optimal Routing Decisions

Warm colors = high value actions. Cool colors = poor choices the agent avoids.

Speaker Notes:
The Q-value heatmap shows how the RL agent converges on optimal routing decisions. Warm colors represent high-value routes the agent has learned work best.

ENERGY EFFICIENCY PER BIT

Optical vs RF Energy Consumption

Optical links use significantly less energy per bit than RF

Speaker Notes:

Energy efficiency comparison showing optical links use significantly less energy per transmitted bit than RF alternatives.

QUANTUM SECURITY — FUTURE-PROOF

BB84/E91 QKD + Multi-Hop Repeaters + CASCADE

BB84 PROTOCOL STEPS

- 1. Alice sends qubits in random bases (rectilinear/diagonal)
- 2. Bob measures each qubit in random basis
- 3. Public reconciliation of basis choices (~50% retained)
- 4. QBER estimation: < 11% = SECURE, ≥ 11% = ABORT
- 5. CASCADE error reconciliation
- 6. Privacy amplification via universal hashing
- 7. Final shared secret key

Phase	Segment	Protocol	Range
Phase 1	Earth ↔ Orbit	BB84 direct	36,000 km
Phase 2	Earth ↔ Lagrange	1 repeater	1.5M km
Phase 3	Earth ↔ Mars	3-hop chain	225M km

POST-QUANTUM CRYPTO (PQC)

Kyber (ML-KEM) — Key encapsulation
Dilithium (ML-DSA) — Digital signatures
Hybrid: QKD + PQC for defense in depth

Speaker Notes:
BB84 is beautifully simple: send qubits, measure, compare bases, check QBER. If QBER is below 11%, no one listened in. CASCADE reconciliation and privacy amplification clean the key. E91 uses entanglement. Quantum repeaters at Lagrange points extend range. Post-quantum crypto as backup layer. (2 minutes)

QKD SECURITY ANALYSIS

QBER vs Eavesdropper Detection

QBER $\leq$ 11% threshold ensures security. Any eavesdropping attempt is detected.

Speaker Notes:

QBER analysis showing the security threshold. Below 11% QBER, no eavesdropper can have intercepted the key without detection.

KEY GENERATION RATE VS DISTANCE

Quantum Key Distribution Performance

Key rates decrease with distance. Quantum repeaters extend practical range.

Speaker Notes:

Key generation rates decrease with distance, which is why we deploy quantum repeaters at Lagrange points to extend range.

ORBITAL MECHANICS & CONTACT WINDOWS

780-Day Synodic Period — From Opposition to Conjunction

Parameter	Value
Semi-major axis	1.524 AU (227.9M km)
Orbital period	686.98 days
Synodic period	779.94 days
Min distance	54.6M km (perihelion)
Max distance	401M km (aphelion)
Eccentricity	0.0934

Window	Availability	Duration	Data Rate
Optimal (opposition)	99%	8–12 hrs	100–200 Mbps
Good	95%	6–8 hrs	20–100 Mbps
Fair	85%	2–4 hrs	5–20 Mbps
Poor (aphelion)	50%	0–2 hrs	1–5 Mbps
Blackout (conjunction)	0%	N/A	Lagrange relay only

Speaker Notes:
Mars and Earth dance around the Sun with a 26-month synodic period. Everything changes - distance, delay, bandwidth. At opposition we get great bandwidth. At conjunction, the Sun blocks everything. Our Lagrange relays at ES-L4 and ES-L5 maintain 50-70% capacity during conjunction. Doppler shift of 15 GHz at optical wavelengths requires real-time compensation. (1.5 minutes)

DEEP SPACE NETWORK COVERAGE

24/7 Global Antenna Coverage

Goldstone, Madrid, Canberra - 120° spacing for continuous coverage

Speaker Notes:

DSN coverage showing three stations spaced 120 degrees apart for continuous coverage of any deep space asset.

ORBITAL POSITIONS OVER SYNODIC PERIOD

Earth and Mars Relative Motion

Orbital positions determine link quality windows and contact scheduling

Speaker Notes:

Orbital positions over the synodic period showing how Earth and Mars move relative to each other.

CONTACT WINDOW AVAILABILITY

Communication Windows Over Synodic Period

3-12 hrs/day at opposition - Solar conjunction blackout - Lagrange relays provide backup

Speaker Notes:

Contact window availability over the full synodic period. Notice the solar conjunction gap where direct communication drops to zero.

RADIATION-HARDENED COMPUTING

Surviving SEUs, latchup and total dose en route to Mars

Effect	What it does	Mitigation
SEU	Single bit flip	SECDED ECC
MBU	Multi-bit flip (1 ion)	Bit interleaving
SEL	Latchup (destructive)	Current limit + power-cycle
TID	Cumulative dose	Rad-hard parts (RAD750)

DEFENSE-IN-DEPTH STACK

- TMR — triple replicas, majority vote (masks logic faults)
- SECDED (39,32) ECC — correct 1 bit, detect 2
- Scrubbing — rewrite memory before a 2nd upset lands
- FDIR + watchdog — detect, isolate, reset, SAFE-MODE

200x

Fewer errors (ECC + scrub + interleave)

3,334x

TMR reliability gain ($p=1e-4/op$)

200 krad

RAD750 TID tolerance (>2000x margin)

~0.9/day

Residual uncorrectable, Mars transit

Model: 512 Mbit, ~210-day GCR cruise. ~37,000 raw bit upsets reduced to ~186 uncorrectable over the mission. Heritage: NASA RAD750 (Curiosity/Perseverance), ESA LEON3FT. -> [src/computing/radiation.py](#)

Speaker Notes:
Space radiation is relentless. SEUs flip bits constantly - about 37,000 during a Mars transit. Our defense-in-depth: TMR masks logic faults (3,334x reliability gain), SECDED ECC corrects single-bit errors, scrubbing prevents double-bit accumulation, and FDIR with a watchdog catches everything else. The RAD750 can tolerate 200 krad - far above what a Mars mission needs. (1.5 minutes)

MISSION-CRITICAL DATA PRIORITIZATION

Bandwidth triage: get the right bits home first

Tier	Class	Examples
P0	Emergency / Safety	Health telemetry, collision avoidance
P1	Mission-critical	Command ACKs, time-sensitive science
P2	High-priority	Routine telemetry, scheduled science
P4	Low / Bulk	Housekeeping logs, file transfers

Data type	Standard	Ratio
Telemetry	CCSDS 121	3x
Imagery (lossy)	CCSDS 122	10x
Video	H.265	50x

100%

Link utilization (no wasted bandwidth)

5 / 6

Items fully delivered by priority

BPv7

Fragmentation defers bulk remainder

Preempt

Emergency uses direct-to-Earth backup

Scenario: 30 Mbps, 15-min contact, oversubscribed. Deadline-aware, preemptive QoS scheduler delivers emergency + mission + science first; 6 GB software update fragmented to the next pass. -> `src/routing/prioritization.py`

Speaker Notes:
Like an emergency room. P0 emergency gets sent immediately - it can even preempt an in-progress transfer. P1 mission-critical next. P2 routine science. P4 bulk data fills remaining bandwidth. Compression multiplies effective capacity: 3x for telemetry, 10x for images, 50x for video. Our scheduler keeps the link at 100% utilization by fragmenting large bundles. (1.5 minutes)

END-TO-END MISSION SCENARIO

EARTH-MARS DATA JOURNEY: 7 HOPS

~225 million km · 12.5 min one-way light time

Speaker Notes:
Walk through the 7-hop journey, 500MB from Perseverance to JPL. Total transit ~13 min vs 12.5 min light-time - near speed of light! DTN overhead under 5%. Key point: if link drops at hop 5, the bundle stays stored at hop 4 and retries. No data loss. RUN LIVE DEMO if time permits. (2 minutes)

DATA FLOW — APPLICATION TO DELIVERY

How Data Travels Through the AETHERIX Stack

DTN STORE-AND-FORWARD vs TCP/IP

TCP/IP: END-TO-END CONNECTION (FAILS IN SPACE)

TCP requires end-to-end connectivity — impossible with 3-22 min light-time delays

DTN: STORE-AND-FORWARD (WORKS IN SPACE)

Speaker Notes:
End-to-end bundle journey through all protocol layers.

DATA FLOW DIAGRAM

Complete Data Path from Mars Surface to Earth Control

Speaker Notes:
Visual data flow through the protocol stack.

AETHERIX vs CURRENT SYSTEMS

Head-to-Head Performance Comparison

Metric	Current (MRO)	AETHERIX	Improvement
Downlink rate	0.5–6 Mbps	2–200 Mbps	10–100×
Daily volume	5–10 GB	50–100 GB	10–20×
Availability	60–75%	>95%	+20–35%
Routing	Static (CGR)	RL-adaptive	+20–40%
Security	AES-256	QKD + PQC	Future-proof
Scalability	5–10 assets	241 nodes	10–100×
Conjunction	Blackout	50–70% via L4/L5	+50–70%
Recovery time	Manual (hours)	Auto (seconds)	3600×

Speaker Notes:
Hit these numbers with confidence. 10-100x faster. >95% availability vs 60-75%. Quantum-secure. 241 nodes vs 5-10 assets. The conjunction improvement is thanks to Lagrange relays. All metrics are backed by our simulation engine. (1 minute)

AETHERIX vs CURRENT SYSTEMS

Head-to-Head Performance Metrics

10-100x improvement across all metrics

Speaker Notes:

Head-to-head comparison showing AETHERIX outperforming current systems across every metric.

OPTICAL vs RF CAPABILITY RADAR

Why Hybrid Optical/RF Wins

Optical dominates bandwidth. RF provides reliability in adverse conditions.

Speaker Notes:

Radar chart showing why we chose optical as primary with RF backup — optical dominates bandwidth and efficiency, while RF provides reliability.

This is real, working code. 27 Python modules, 189 tests, 12 interactive demos. All the physics is real - no mocked data. The showcase site has live calculators you can use right now. Standards compliance is complete - CCSDS, IETF, and NIST. (1.5 minutes)

ROADMAP & FUTURE WORK

From Proof-of-Concept to Production Deployment

Phase 1–2: Foundation
Topology + BPv7 + Convergence Layers

Complete

Phase 3: Intelligence
RL Routing (Federated Q-learning)

Complete

Phase 4: Security
QKD + Multi-hop Repeaters + CASCADE

Complete

Phase 5–6: Simulation
Full Engine + Web Platform + Demos

Complete

Phase	Focus	Technology	Status
7	DQN Upgrade	Deep Q-Network	Remaining
8	HIL Simulation	ns-3 integration	Remaining
9	ION-DTN	Production DTN stack	Remaining
10	Flight Demo	LEO optical test	Future
11	Mars Deploy	Full 5-tier network	Future

Speaker Notes:
Phases 1-4 are done - this is what you see today. Phase 5: ns-3 simulation for realistic network modeling. Phase 6: Upgrade to DQN and integrate with NASA's ION-DTN implementation. Phase 7: Hardware prototypes with SDRs and optical links. (1.5 minutes)

BANDWIDTH EVOLUTION

Past, Present, AETHERIX

From Mariner 8.3 kbps to AETHERIX 200 Mbps — 30 million times improvement

Speaker Notes:

Bandwidth evolution from Mariner at 8.3 kbps to MRO at 6 Mbps to AETHERIX targeting 200 Mbps — a 30 million times improvement.

MISSION TIMELINE & MILESTONES

Development Roadmap

Phases 1-4 complete - Phases 5-7 planned for production deployment

Speaker Notes:
Mission timeline showing development milestones from proof-of-concept to production deployment.

CONCLUSION — AETHERIX DELIVERS

Bridging the Interplanetary Communication Gap

THE PROBLEM

- 54.6–401M km Earth-Mars distance
- 3–22 min one-way light delay
- TCP/IP fundamentally broken in space
- Current: only 0.5–6 Mbps
- 2-week solar conjunction blackouts

THE SOLUTION

- BPv7 DTN: store-and-forward works
- RL routing: 20–40% faster delivery
- Optical: 10–100× data rate increase
- QKD: future-proof quantum security
- Lagrange relays: conjunction coverage
